## AMENDMENTS TO THE CLAIMS:

This listing of claims will replace all prior versions, and listings, of claims in the application:

## LISTING OF CLAIMS:

1.(currently amended) Method A method for generating application software for managing a process, characterized by the fact that said method implementing a system software that is common to all of the application software and that said method includes: generated by said method, said method comprising:

cybernetically representing said process in a set for tasks and in relationships between the tasks;

breaking down each task into sub-blocks of tasks, until all actions of the process are described using at least one diagram composed of components including a root, branches, nodes and leaves, whereby each of the components is represented by an action corresponding to a generic object of an attributing class;

transcribing each object of each diagram into an attributed generic object by capturing data in predetermined formats associated with said attributes by using a capture interface associated to each class of generic object;

automatic precompiling to verify that the attributed objects required for an operation logic of the application are present and are supplied appropriately in terms of syntax;

automatic compiling during which data description of the attributed objects are integrated and are assembled with the system software to produce an executable application software; and

executing executable software of the application.

- a process representation stage (32) that implements a very small number of classes of actions or generic objects, typically less than 20, in at least one diagram of the application;
- a stage (33) for transcribing each object of each diagram into an action corresponding to an attributed object, whereby during the transcription stage each class of action or generic object is associated with an application data capture interface;
- a stage (34) for transcribing the nodes, branches, and leaves of each diagram into an action corresponding to an attributed object;
- a precompilation stage (35) during which it is verified that the object attributes required for the operating logic of the application are present and are supplied appropriately in terms of syntax;
- a compilation stage (36) during which the data descriptors of the attributed object are integrated and are assembled with the system software to produce an executable application software; and
- a stage (37) for execution of the executable application.

Docket No. 0608-1024 Appln. No. 10/509,992

- 2.(currently amended) Method The method according to claim 1, wherein[[,]] during the object transcription transcribing stage [[(33)]], at least one action launches a complete processing cycle that is located at a remote location of a tree structure that corresponds to at least one diagram and, once said processing cycle is completed, returns to its starting point, wherein local code makes a call to remote code which returns to the local code upon completion.
- 3.(currently amended) Method The method according to claim 1, wherein, during the execution executing stage [[(37)]] the executable application software implements a library for managing [[the]] a sequence of events corresponding to the abovementioned at least one diagram, whereby said library constitutes an automaton [[(70)]] that manages the sequence of events of the processes and executes [[the]] operations that checkpoint them, whereby the sequences of events of the operations are defined in [[the]] an application referential, by means of the method [[(10)]], by describing [[the]] actual data flows.
- 4.(currently amended) Method The method according to claim 1, wherein, during the compilation compiling stage [[(36)]] or the execution executing stage [[(37)]], the method employs an engine [[(71)]] that includes an executive that is responsible for recognizing [[the]] a hardware and communication configuration.

- 5. (currently amended) Method The method according to claim 4, wherein the engine [[(71)]] manages one or more databases according to a data file descriptor that is provided by [[the]] an application referential, that is, comprising a list of [[the]] information contained in each file and [[the]] list of [[the]] access indices, whereby a list of the fields constitutes wherein each of these indices is a list of fields, [[the]] and links between [[the]] multiple encodings of a single item in multiple services, multiple sites, or multiple companies.
- 6. (currently amended) Method The method according to Claim 5, wherein the databases are synchronized according to a schedule that is determined by the diagram, upon demand, or before certain predefined events.
- 7. (currently amended) Method The method according to claim 1, wherein the object transcription transcribing each object stage [[(33)]] includes, for programming each action:
- i) a naming stage (331) during which a name is given to said action;
- ii) a function <u>definition</u> <u>defining</u> stage <del>(332)</del>, during which said action is identified with a task; and
- iii) an information <u>definition</u> <u>defining</u> stage <del>(333)</del> during which the information that will be processed in the action is identified.

Docket No. 0608-1024 Appln. No. 10/509,992

- 8. (currently amended) Method The method according to Claim 7, wherein the compilation compiling stage [[(36)]] replaces the action name that is given by the transcriber during the naming stage (331) with an index in a task table.
- 9. (currently amended) Method The method Method according to claim 1, wherein, during the representation representing stage [[(31)]] and transcription transcribing stage (32, 33), said at least one diagram corresponds to at least one tree structure in which the nodes and leaves, where the code is implemented, are made up of actions, whereby [[the]] return values of these actions determine [[the]] movement in the tree structure.
